**Historic Archaeological Component Form Instructions**

This form should be completed for each historical resource with archaeological potential and attached to a completed *Management Data Form*. Additional copies of the form may be used to describe individual features. Please note at the top of the form if the form pertains to the historical archaeological component in general or to a particular feature. Please see the *Colorado Cultural Resource Survey Manual* for detailed information concerning many of these categories.

1. **Resource Number:** Please put the resource number (Smithsonian trinomial number) here, as it appears on the *Management Data Form*.

2. **Temporary Resource Number:** List any temporary numbers assigned in the field.

3. **Site Name:** Please put the site name here, as it appears on the *Management Data Form*.

4. **Site or Feature:** Check if this form pertains to the entire site in general. If no, please supply a feature/structure number or name to which the form applies.

5. **Site, Component, or Feature Type:** Describe the type of site/feature, specifying function if known. Examples of site, component, or feature types can be found in Appendix A of these instructions.

6. **Narrative History:** The narrative history should be focused on the history of this property and directly pertain to the property’s historic significance and integrity. The description should include both a synthesis of the artifacts and features and any additional important information. You may wish to complete parts 19, 22, and 24 before writing this section. Please see National Register Bulletin: How to Complete the National Register Registration Form page 47, [http://www.nps.gov/nr/publications/bulletins/nrb16a/](http://www.nps.gov/nr/publications/bulletins/nrb16a/)

   This narrative is the most important section of the form. Please be as complete as possible.

7. **N.R.H.P. Historic Landscape:** Indicate, by checking the appropriate box, whether the resource is located in a cultural or historic landscape. A cultural landscape is defined as "a geographic area, including both cultural and natural resources and the wildlife or domestic animals therein, associated with a historic event, activity, or person or exhibiting other cultural or aesthetic values." There are four general types of cultural landscapes, which are not mutually exclusive: *historic sites, historic designed landscapes, historic vernacular landscapes, and ethnographic landscapes*. (see [http://www.nps.gov/nr/publications/bulletins/nrb30/nrb30_8.htm](http://www.nps.gov/nr/publications/bulletins/nrb30/nrb30_8.htm) - National Register
Bulletin 30 *Guidelines for Evaluating and Documenting Rural Historic Landscapes* for more information).

8. **Component or Feature Description:** If the form pertains to a particular component or feature of the overall site, please describe it here in full. Be as specific as possible concerning the component or feature function, and location within the overall site.

9. **Historic Component Date(s) and/or Sociopolitical Period:** Give date or range of dates of the historic component, being as specific as possible (e.g., 1810-1830, rather than the early 1800s). It may be appropriate to also reference the sociopolitical period (The Depression, The Civil War, etc.) corresponding to these dates here. Describe the criteria used to date the site (e.g., diagnostic artifacts, patent dates, map). Provide the citation for the source(s) where data was gathered.

10. **Component Function(s):** If possible, identify the original and present uses of the site, being as specific as possible. If the site has been abandoned, indicate that in present use. If a site has had multiple uses or has multiple components with different uses, please elaborate.

11. **Ethnic Affiliation of Occupants:** When known, indicate the ethnic affiliation of site occupants (e.g., Euroamerican, Hispanic, etc.). The preference is for “Historic” for generic historic cultural affiliation over “Euroamerican” (or its variants). Although “Historic” is not a culture it is recommended as a placeholder that demonstrates that consideration of culture has taken place. In cases where an ethnic affiliation has been identified though historical records or site elements, the culture should be identified by country of association such as Germany, other comparable ethnic identifier (such as Basque, Hispanic, or African American), or Native American group. Describe the criteria you used to determine affiliation (e.g., artifacts or architectural features, historic references, etc.)

12. **Historic Boundary:** Select boundaries that encompass the entire resource, with historic and contemporary additions. Include any surrounding land historically associated with the resource that retains its historic integrity and contributes to the property's historic significance. The historic boundary may not match the legal property ownership.

For more information on historic boundaries, see: 

13. **N.R.H.P. Area of Significance:** List the aspect of historic development in which this property made contributions for which it meets the National Register criteria, such as agriculture or politics/government. See http://www.nps.gov/nr/publications/bulletins/nrb16a/nrb16a_III.htm#statement for a listing of areas of significance. Provide the citation for the source(s) where data was gathered.

14. **N.R.H.P. Period of Significance:** List the span of time in which a property attained the significance for which it meets the National Register criteria. This could be a specific
date or a date range. A property can have multiple periods of significance based on the appropriate areas of significance. If this is the case, list the multiple periods of significance. Provide the citation for the source(s) where data was gathered.

15. **Theme**: List the themes found in Appendix A of this document that pertain to the site.

16. **Eligibility Support**: If you are using this component form to document only a portion of the site, please check whether or not the portion you are recording supports the N.R.H.P. eligibility of the entire site. Justify your selection below. If you are using this component form to record the site in its entirety, check the N/A box.

17. **Recorder(s)**: Enter the full name of the recorder(s). Do not use initials.

18. **Date**: Enter the last day that you were in the field. The date should be in a MM/DD/YYYY format.

19. **Presence and Quantity of Artifacts**: Use this table to denote what artifacts you are seeing, and how many. Note that many of the artifact types have dates associated with them. Use approximations for large quantities of artifacts. Use this information to help you fill out field 9 above.

20. **Assemblage Size**: Enter the total number of artifacts on the site, or check the appropriate estimated box.

21. **Artifact Density**: Check high, medium or low for artifact density. In description, indicate if there are differences in artifact distribution (e.g., heavy in some areas and light in other areas).

22. **Unique Artifact Descriptions**: List specific artifact types and the important attributes in the description field. The form contains prompts concerning the important descriptors for each artifact class. All of these items should be included in the counts of the Artifact table above in item 19 – Presence and Quantity of Artifacts. This gives you the opportunity to call attention to the really cool stuff.

   For a detailed discussion of the different artifact classes and their important diagnostic characteristics, please see Appendix B, *Historic Artifact Handbook*, to these instructions. It will be very helpful to those inexperienced in recording historic archaeology sites and you are encouraged to consult it.

23. **Standing structures**: Indicate whether or not there are standing structures on the site. If there are, please complete an *Architectural Inventory Form(s)* (OAHP 1403) in addition to this form. If there is enough of the structure left to describe its architectural features (e.g., architectural style, number of stories, or presence of chimneys, doors, windows, etc.) you should also complete an *Architectural Inventory Form(s)*.
If you complete an *Architectural Inventory Form(s)* please reference them here. You don't need to repeat any descriptive data that is redundant to the 1403 forms.

24. **Features**: List and describe each feature on the site. Be as specific as possible about function (e.g., is trash related to domestic or construction activities? Use cabin or barn vs. structure). In the case of trash scatters, artifacts should also be accounted for under the artifact section(s) of this form. The "Feature/Number Name" is a symbol or identification number referring to a feature on the sketch map.

For architectural features, include available information on construction material (e.g., wood, stone, etc.) and feature dimensions (preferably in feet and inches rather than metric). Include building footprint or groundplan here when it is discernible.

25. **Archaeological Potential**: Note whether or not there is the potential for archaeological deposits. If there is, describe the location and summarize the potential nature, depth, and research potential for those deposits. If it is unknown, document those areas that might have potential, which only further work would confirm.

Appendix B

Historic Artifact Handbook

by

Jonathon C. Horn
Alpine Archaeological Consultants, Inc.
PO Box 2075
Montrose, CO  81402

March 2005

The intent of this handbook is to provide site recorders with little or no background in historic artifact identification sufficient information so that they can provide consistent descriptive information about the artifacts and site features they are observing. Good description of observed features and artifacts is essential for functional and chronological determinations to be made, thereby insuring that sites or site components are evaluated for significance using the proper thematic context. Regardless of whether or not an individual has the expertise to interpret the evidence present at a particular site, anyone carrying out site recordation has the obligation and should have the ability to provide good descriptive information.

A large portion of this handbook is composed of illustrations. For the most part, these are self-explanatory and little text will be written to accompany them. Many artifacts will not be described whatsoever. A list of references is also provided. The focus of the handbook will be on commonly found artifacts that are particularly useful in providing dating information. Historic artifacts from the late nineteenth and twentieth centuries are particularly time sensitive, because of the rapid growth and change of technology. Using an assemblage of historic artifacts, it is not uncommon to be able to date a site to a 5 or 10-year time period. Functional interpretations can also be quite accurate using the artifacts alone. When coupled with well-directed historical research, the information that can be learned from a historic site can be very illuminating, not only from a historical perspective, but from anthropological, behavioral, technological, and socioeconomic viewpoints as well.

When classifying historic artifacts, the preferred method is by function. Classifying artifacts by material type makes functional interpretations very difficult and is inherently troublesome because many historic artifacts are composed of a variety of materials. A classificatory system for artifacts in museum collections was devised Robert G. Chenall (1978) and updated by Blackaby and Greeno (1988). This system is used by the National Park Service for their museum collections and works very well, especially when reference is made to Sprague (1981). Reuse of artifacts for purposes other than their original intention is very important data and should be recorded, but is problematic.

Vessel Glass

Vessel glass includes all glass containers such as food and household chemical bottles and jars, beverage bottles, and canning jars. It also includes glass service wares such as drinking glasses and dishes. Glass color is a very good indicator of a vessel's age.

White Milkglass       ca. 1890s-present
Aqua                  ca. 1800-1920s
Green                 ca. 1860s-present
Amber or Brown        ca. 1860s-present
Cobalt Blue           ca. 1890s-present
Purple                ca. 1885-1920
Yellowish             ca. 1918-1950s

Purple glass is one of the best time markers to be found on archaeological sites. Use of manganese as a clearing agent in glass became very commonplace by 1885, perhaps beginning as early as 1880. Although the vessels
started out clear in color, exposure to the sun resulted in a purple tint, varying in intensity depending on the amount of manganese used. The main source of manganese, Germany, was cut off as a result of World War I. Supplies on hand may have lasted into the very early 1920s, though in very limited quantities. Selenium replaced manganese as a clearing agent. It also changed color with exposure to the sun, this time to a yellowish hue, never getting dark enough to be confused with amber or brown glass.

Care must be taken when assigning a disposal date for a particular piece of glassware. Common food or household vessels were most usually disposed of immediately or soon after their contents had been used up. Canning jars and table service, especially fancy glassware, were used over and over again and were not discarded until unusable. Other glassware fragments, such as lamp chimneys or lantern globes, may be mistaken for short-lived vessels but in reality were used until broken.

Makers marks are very commonly found on the bases of food or household bottles and jars and the name or trademark of the product manufacturer is also frequently embossed on containers or lids. These marks and names should always be recorded as accurately as possible, even if fragmentary, because they can be looked up with relative ease, providing dates and other information. Here are four of the most common makers marks:

⊕ - Mark of the Owens Bottle Company in use between 1911 and 1929 (Toulouse 1971:393).
⊗ - Mark of the Owens Illinois Glass Co. of Toledo, Ohio used upon the merger of the Owens Bottle Company and the Illinois Glass Company in 1929 and used until 1954 (Toulouse 1971:403-406). Associated with this mark will be numbers to the left, right, and bottom. The number to the left indicates the manufacturing plant. The number to the bottom is the mold number. The number to the right is the date number and can usually be added to 1930 to get the year of manufacture. Bottles from the early 1940s were marked with a single date digit to the right of the mark that may cause confusion with bottles manufactured in the early 1930s. Although some bottles from 1940 were simply marked with a 0, others were marked with a dot following the 0. This use of a dot to designate a 1940s age continued until a two digit date mark was instituted. Still, the single digit and dot designation may be found on bottles through 1946, though the two digit markings began in 1943. Further confirmation of a 1940s age is that stippling is commonly found on the base of these bottles, which is an indication that the glass is Duraglas, which began to be used in 1940 (Lockhart 2004, 2006). An exception to the dating formula was on very small medicine bottles where accompanying numbers were left off entirely or only a single date digit was used into the 1950s (Lockhart 2004, 2006).

∥ - Mark of the Hazel-Atlas Glass Co. of Wheeling, West Virginia. This mark was in use from 1920 to 1964 (Toulouse 1971:239). According to the U.S. Patent Office, the trademark was registered in 1924.

Other marks also seem to have date numbers in association, particularly beer bottles beginning in the 1940s. These are not well documented, so assumptions of dates by numbers on bottle bases should be considered relative to other artifacts on a site. Plastic bottles may also have date numbers.

Vessel manufacturing attributes should be recorded as well. The attached dating key and illustrations provide the technical information necessary for providing this information.

Depression glass comes in a variety of colors and shapes. It was usually inexpensive dime-store dishware and was often given away in advertising promotions. Patterns can often be identified and frequently have restricted periods of production. On occasion, decorative glass table service or housewares came in purple. Consideration should be of the type of vessel and its use when purple glass is concerned as curated items or items considered for long use were sometimes manufactured of purple glass that, without close observation, can be confused with fragments of jar or bottles of an earlier age.

Ceramics

Ceramics found on archaeological sites in the West can generally be categorized into one of three basic types: stoneware, earthenware, and porcelain.
Stoneware is a clay ceramic frequently used for utilitarian vessels, such as crockery or sewer pipe. It is fired at a high enough temperature that the clay becomes vitrified somewhat, resulting in impermeability to liquids. It is frequently glazed. The fired clay has a rather porous appearance and is frequently tan to brown.

Earthenware is probably the most common type of ceramic found on historical archaeological sites. It is easily manufactured into a variety of shapes with fairly thin walls and is impermeable to liquids. The fired clay appears very fine in texture, ranges in color from white to yellowish, and sticks to the tongue to varying degrees depending on how vitrified the ceramic is from firing. Earthenwares are commonly glazed with a white or clear slip and are often well decorated. Decoration can range from blue-on-white oriental patterns to polychrome hand-painted, transfer-printed, or decal decoration, to relief-molded patterning with gilding, or any combination of the above. In general, the more refined the decoration, the more expensive the ware. This makes some economic scaling possible. Another generalization that should be considered is that decorated wares frequently indicate a family unit or at least the presence of a woman. Plain white earthenwares, often known as hotel ware, are frequently found at labor camps.

Porcelain is the most refined of the ceramics. It is generally very thin walled and highly vitreous. In cross section, porcelain looks very much like rough glass and will not stick to the tongue. It is almost always very fancy tableware and well decorated in the manner described above for earthenware. The expensiveness of porcelain is indicative of a certain level of affluence and, again, the likelihood of a woman's presence.

As with vessel glass, makers marks are very commonly found on the bases of earthenware and porcelain vessels and on the sides of stoneware vessels. These are either printed on or impressed into the vessel. Makers marks are very time diagnostic and occasionally can be dated to the month and year of manufacture. Because ceramic vessels were intended for long use, the date obtained from ceramics may indicate a slightly earlier date than is the actual case for a site. Ceramic dates should be considered as only one piece of information in the total artifact assemblage from a site when ascribing a date.

Cans

Cans come in a wide variety of shapes, sizes, and styles. Changes in can manufacturing technology in the late nineteenth century and early twentieth century make cans fairly good time indicators. The most commonly encountered cans are those which contained fresh foods. These can be broken down into three basic types: Hole-in-cap, hole-in-top, and sanitary (modern-style) cans.

Hole-in-cap cans are lead-sealed cans having a separate filler cap, soldered in place, with a pin hole vent covered with a spot of lead solder. These cans were manufactured at first entirely by hand and later by machine. The ends of the cans have flat lips that fit around the outside of the can sides. The connection is not interlocked in any way. One end of the can has a filler hole large enough for the contents of the can to enter. The filler hole was covered by a sheet metal disc soldered in place forming a characteristic ring of lead. The filler cap has a pin hole which allowed steam to escape during processing. Once processing was completed, the pin hole was sealed with a spot of lead solder. The side seam of the cans was also covered with a line of solder. In general, cans from the early 1880s and before tend to have heavier amounts of solder on their side seams, less neatly applied, than later cans. Side seams began to be soldered by machine in the 1880s, resulting in more uniform and regular solder seams. Aberrations may be observed on hole-in-cap cans that may be noteworthy. On occasion, cans may be found that have the sides fitted around the ends. More frequently, cans with two vent holes and two lead spots on the filler caps may be observed.

Hole-in-cap cans were in production by the 1820s. A stamping machine for the manufacture of can ends was patented in 1847. Can ends began being soldered by machine in the mid-1870s and a machine for soldering side seams was introduced in 1883. Rectangular hole-in-cap cans for canned corned beef were introduced in 1875 (Rock 1984:102-103). Inventions for crimping the seams of cans, eliminating the need for solder, leading to the development of "sanitary" cans, began in 1888, but sanitary cans as we know them did not come onto the market until 1904. By 1911, sanitary cans had dominated the can market (Rock 1984:105-106). In general, hole-in-cap cans on a site indicate a date of occupation prior to 1914 and an absence of sanitary cans suggests a pre-1904 date. One exception should be noted. Large hole-in-cap bulk food cans provided by the U.S. government to Civilian Conservation Corps camps, and possibly for military use, have been noted dating to the 1930s.
Hole-in-top cans closely resemble hole-in-cap cans but do not have filler holes. The tops of these cans may be stamped with ridges that mimic filler holes, but lack the solder ring. They do have a pin hole vent sealed with a spot of lead. Hole-in-top cans were introduced in 1900 by Carnation for evaporated milk (Rock 1984:104). These cans were still in use until the early 1990s. Prior to the introduction of hole-in-top cans (by 1885), evaporated milk was canned in hole-in-cap cans.

Sanitary cans are the cans in use today. These were the result of innovations in seam crimping machinery. In 1897, machinery was developed that could crimp the can ends to the sides with a double seam sealed with a rubber compound. By 1904, sanitary cans were in full production, completely dominating the market by 1911.

Other Can Innovations of Note

During the late 1890s and early 1900s, many new innovations were attempted to modernize food cans. These innovations appear as cans with unusual attributes. For instance, some lead-sealed cans have been observed with crimped ends similar to sanitary cans with lead spots over vent holes similar to hole-in-top cans. Some hole-in-cap cans have been observed with lead spots over two vent holes through the filler caps.

Prince Albert tobacco tins appear to have been first manufactured in 1907 or 1908 (Rock 1989:166; Periodical Publishers Association 1934:74). They had a simple friction-type lid with a loose pin hinge. In 1948, the lid was changed to be more airtight. The edge of the can was doubled over and the lid was made with a U-shaped lip into which the can edge fit and ran the full length of the lid. This is the closure still used (Kirkpatrick and Duran 1981:53).

Round quart-sized motor oil cans were introduced in 1933 (Rock 1989:147).

Sardine cans: three-piece body – 1810-1880; one-piece body – 1880-1918; depressed lid – 1884-present; double seamed – 1918-present (Gillio et al. 1980:9)

Distribution of canned beer did not begin until 1935. Cone-top cans with crown cap finishes were used on a limited basis from 1935 to 1959 (Rock 1981:25). See Beer Can Table for additional information.

Soft drinks were not successfully canned until 1953 (Rock 1981:27).

Can Openings

The way in which food cans have been opened is an indication of what may have been inside. There appears to be a correlation of the size of the filler hole on hole-in-cap cans to the type of opening technique used. This is not surprising because both are related to the size of the items inside. The opening technique may indicate whether the food inside was liquid, solid, or composed of small or large pieces. Condensed milk cans tend to have two small punched holes or slits for pouring out the contents. Key-wind openings were first introduced in 1866, though they were not widely used. In 1895, the technology was refined for use on meat tins that incorporated a scored strip (Rock 1984:105; Gillio et al. 1980:9). This is the opening technique used until very recently on sardine and coffee cans. Geared rotary can openers were introduced in 1925 for use on sanitary cans. Church-key openers were introduced in 1935 (Gillio et al. 1980:9).

Marks on Cans

For the most part, food cans were identified with paper labels and others with painted labels that rarely survive in archaeological contexts. Certain can types, such as baking powder cans, coffee cans, and others, have embossing identifying their contents and/or manufacturer. It is frequently possible to look these up and refine the date of the artifact. An unusual example is KC Baking Powder cans that give a number of years that the product cost the same. The year of manufacture can be determined by adding the years to 1890. Later cans, such as hole-in-top and sanitary cans, occasionally have markings or codes which may prove to be informative and should be recorded. For instance, the “SANITARY” mark found on some early sanitary cans is probably the mark of the Sanitary Can Company, which began business in 1904 and was purchased by the American Can Company in 1908 (Rock 1989:65).
Plastic

Molded plastic screw caps began to be manufactured in quantity in 1927. Initially, they were used on high-priced toiletries and cosmetics and were black, dark red, or brown in color. New plastics enabled a wide variety of colors to be manufactured in a few years, as well as a wider variety of applications. With improvements in molding equipment, plastic screw caps could be produced at prices competitive with metal caps (Lief 1965:30).

Nails

Nails are the most frequently encountered hardware fasteners at historical archaeological sites. The basic identification of wire (round) and cut (square) nails and their relative frequencies to each other is an important dating tool.

Cut nails have a long history of manufacture. Both hand-made and machine-made cut nails were manufactured in the nineteenth century. Transition from cut nails to wire nails took place between the 1880s to the early 1900s. Wire nails began to be imported in small numbers to America in the 1850s, and the manufacture of wire nails in America began in 1873; large-scale production did not begin until the 1880s. Wire nails were initially most competitive with cut nails in the smaller, finer sizes. It has been estimated that by 1890, approximately 50% of the nails produced were wire nails. In 1894, 70% of the nails produced were wire nails; in 1900, 82% were wire nails; and in 1913, 95% were wire nails (Clark 1929:Vol. 2:351-355, Vol. 3:126; Buckles 1978). In general, if cut nails are found on a site, a date of 1900 or before can be presumed. The rate at which wire nails replaced cut nails may vary throughout the country depending upon the source of supply. In Colorado, it is common for sites as early as 1890 to have a nail assemblage dominated by wire nails. This seems to be because the Colorado Fuel & Iron Company of Pueblo had the capability of producing wire nails by that time and had the ability to ship them by railroad by way of the Denver & Rio Grande Railway. The sphere of their marketing area is currently unknown, but probably covers all of Colorado and may have extended into northern New Mexico, western Kansas, and southern Wyoming.

Window Glass

Window glass is flat glass, usually light green in color, frequently with lines, air bubbles or other flaws in older examples. The presence of window glass usually indicates that a fairly substantial structure was present at that location. Often, no other physical evidence remains of a structure besides window glass and nails.

Cartridges

Cartridges can be categorized into three types: Pinfire, rimfire, and centerfire.

Pinfire cartridges are the oldest of the patent ignition type cartridges. The hammer of the gun struck a pin projecting from near the base of the cartridge engaging a primer that set off the enclosed load. These saw fairly wide use and were still advertised after 1900.

Rimfire cartridges were ignited by a blow to the base by the gun's firing pin or hammer. These cartridges were introduced in the 1850s and are still popular today.

Centerfire cartridges have a primer incorporated into their base which ignites the load when struck by the gun's firing pin. These cartridges were developed in the 1860s, but did not become generally available until 1873 with the introduction of the .45-70 Government cartridge. Centerfire cartridges are still in use today.

It is very important to record any markings on the base of cartridges. On occasion, cartridges may be found that have no markings. These should be collected so that they can be measured and identified. In general, cartridges with no markings are older varieties, possibly dating prior to the early 1880s. Centerfire cartridges are reusable. Original primers are brass, replacement primers are usually chrome. Reloaded cartridges may not be very good indicators of site age. Introduction of recent cartridges by hunters to an otherwise older site is not uncommon and should be expected and accounted for when considering the occupational history indicated by surface artifacts.
Some basic chronological information about marks on cartridges:

U.M.C. - Union Metallic Cartridge Co. before it merged with Remington in 1912.

Rem-UMC - Remington-Union Metallic Cartridge Co. after merger in 1912.

R-P - Remington-Peters after Peters Cartridge Co. was absorbed by du Pont and Remington in 1934.

W.R.A. Co. - Winchester Repeating Arms Company prior to 1934 when the mark was changed to simply W.R.A.

Military ammunition is marked with the month and year of manufacture as well as the manufacturer.

Other gun related items to look for are percussion caps and gun flints. Gun flints may be mistaken for prehistoric lithic material but has a characteristic square shape. Bullets and gun parts are also found on occasion.

Other Artifacts

Buttons and Fasteners - Buttons and other clothing fasteners are commonly found on historical archaeological sites. Describe buttons by how they are attached to clothing and the material they are made of. Common shirt buttons should be described as two or four-hole sew-through buttons. What are usually thought to be white milkglass buttons are in reality Prosser ceramic. On occasion, the backs of buttons will have the name of the manufacturer or other information. Metal buttons similar to those on Levi's frequently have product names stamped or embossed on them. These are generally from overalls or other work clothes. Overall and suspender buckles are generally made of wire, sometimes partly covered with sheet metal. Old catalogs of clothing are very helpful in their identification.

Buttons - Beads are found at both historic and post-contact aboriginal sites. Beads should be described by how they were made - drawn or spun (wound), by color, and any other manufacturing attributes they might possess such as grinding, etching, engraving, enameling, or painting. Bead styles can be somewhat time sensitive.

Wire Products - Wire products such as barbed wire, baling wire, and wire rope became widespread after the development of the Bessemer steel manufacturing process in 1876. Prior to the Bessemer process, wire could not be made into long strands of consistent strength and quality. The ability to make long lengths of good quality wire enabled a large number of products to be produced. One of the most frequently encountered products is barbed wire. The number of types of barbed wire manufactured is astounding. The varieties are very well documented, however, and patent dates ascertained if good descriptions are made in the field. Baling wire also became quite prevalent. Early baling machines required hand tying off of the ends of wire around a bale of hay. To facilitate this, a variety of bale ties with distinctive pre-made loop ends were marketed. How long these were available is not known, but they were certainly in use through the 1890s. Wire rope (commonly referred to as "cable") consists of numerous strands of wire braided or twisted into a single unit, sometimes around a core of hemp rope. Wire rope replaced natural fiber rope for use with machinery, especially with the expansion of use of steam power in the late 1880s and 1890s. Consequently, when wire rope is found on a site, it can be presumed that some sort of motive power was in use there.

Animal Shoes - Horse, mule, and oxen shoes are easy to identify. When examining them, however, be sure to note any modifications, especially of horseshoes. Such modifications may indicate use for work or pleasure, orthopedic problems the animal may have had, and use in icy, snowy, or muddy conditions - indicating seasonality.

Stove Parts - Very little information is currently available about stove manufacturers. However, stove parts are usually well marked with casting marks, the name of the stove and its manufacturer, and decorations. Frequently these marks can be identified or interpreted. For instance, some marks may indicate the size of the burner plates and oven. Certain parts may indicate whether a stove was intended to burn coal or wood. It may also be possible to tell if a stove was a cook stove or heating stove. Even when pieces of an actual stove are not
present, pieces of stove pipe may reveal that one was there and where it was located. Ash and coal cinders are other indicators.

**Hardware** - Hardware is a very diverse artifact category that must be handled on an item by item basis. Artifacts in this category include all sorts of tools, equipment, and fasteners. Frequently pieces of a larger item are found which cannot be identified from what is left. Sometimes a single item will be very informative. The best that can be done is to describe hardware artifacts as well as possible. If the function of an item is unknown to you, photograph or draw it. It is usually possible to tell if something is hand or machine made. On machine made items, look for casting marks. These will usually be numbers but occasionally are manufacturer's marks, patent dates, or names.

<td>- J-spout cans introduced.</td>
</tr>
<tr>
<td></td>
<td>- Aluminum lids used on steel-bodied cans. These are often described on can labels as &quot;soft-tops.&quot;</td>
</tr>
</tbody>
</table>

Note. It is often difficult (if not impossible) to document the dates when various features are eliminated or removed from use, due primarily to the fact that old stock is frequently utilized after changes have been made. The presence of multiple suppliers (and in some cases, brewery locations) will also result in the simultaneous usage of different styles of cans (i.e., a single brewing company may produce aluminum and crimped-steel cans in different plants).
